Chapter 3 (part 2): Heuristic Search

Adapted from slides available in Russell & Norvig's textbook webpage

Dr. Ahmedul Kabir

Outline

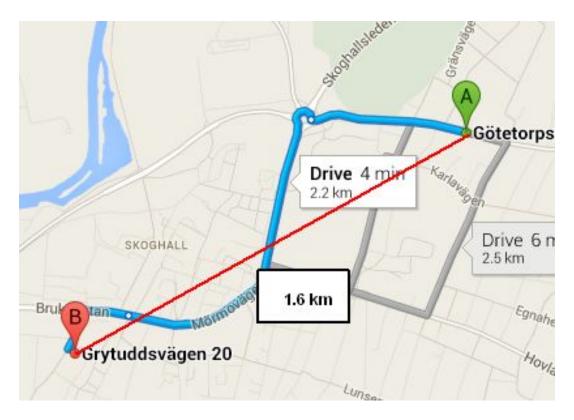

- Heuristics
- Best-first search
- Greedy best-first search
- A* search
- More on heuristics

Definition of heuristics

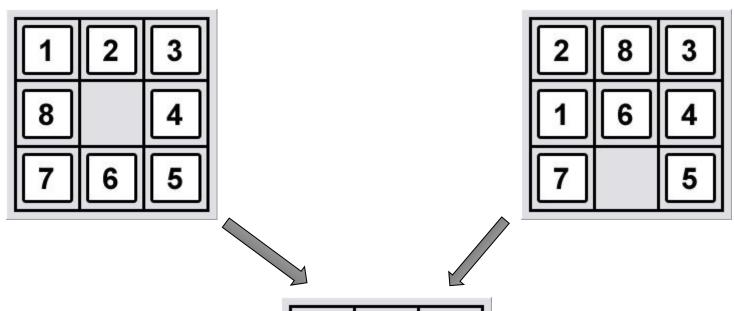

- A heuristic technique (/hjuːˈrɪstɪk/; Ancient Greek: εὑρίσκω, "find" or "discover"), often called simply a heuristic, is any approach to problem solving, learning, or discovery that employs a practical method not guaranteed to be optimal or perfect, but sufficient for the immediate goals.
- Heuristics can be mental shortcuts that ease the cognitive load of making a decision.
- Examples of this method include using a rule of thumb, an educated guess, or common sense.

Example: Driving from A to B

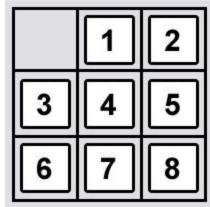

• The straight line distance is a heuristic to estimate the driving distance

Example: 8-puzzle problem

Which state is "closer" to the goal state? How can we quantify this?

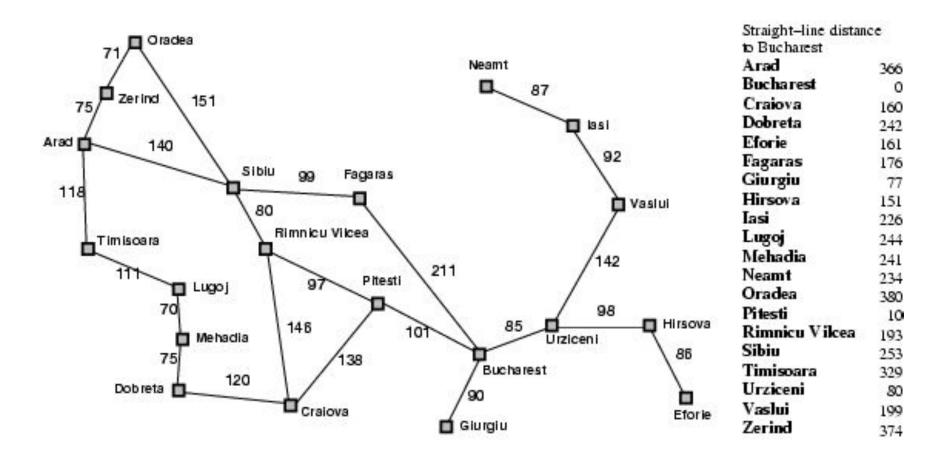

Best-first search

- Idea: use an evaluation function *f*(*n*) for each node
 - estimate of "desirability"
 - Expand most desirable unexpanded node
- Implementation:

Order the nodes in fringe in decreasing order of desirability

- Special cases:
 - Greedy best-first search
 - A* search

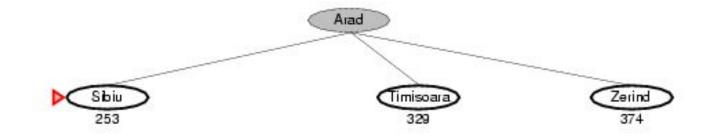

Romania with step costs in km

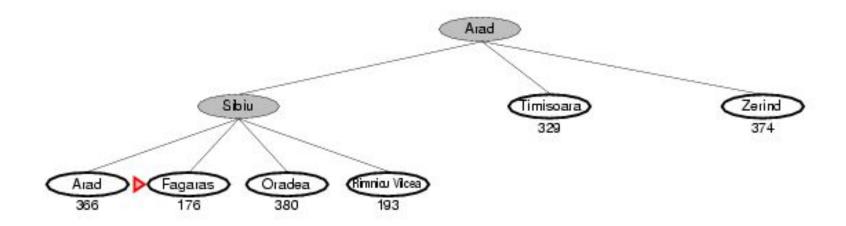

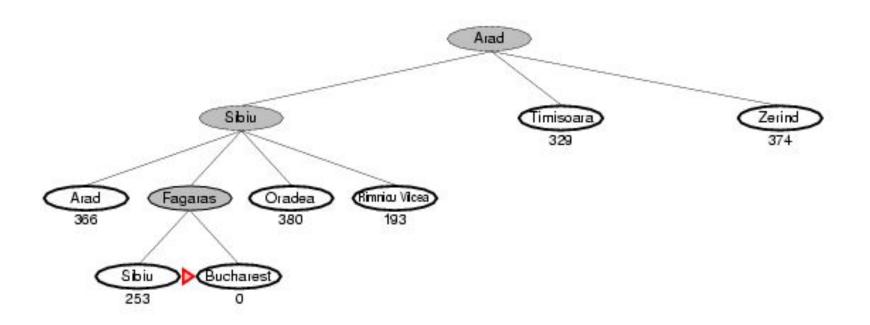

Greedy best-first search

- Evaluation function f(n) = h(n) (heuristic)
 - = estimate of cost from n to goal
- e.g., $h_{SLD}(n)$ = straight-line distance from n to Bucharest
- Greedy best-first search expands the node that appears to be closest to goal

Properties of greedy best-first search

• <u>Complete?</u> No – can get stuck in loops, e.g., when going from Iasi to Fagars:

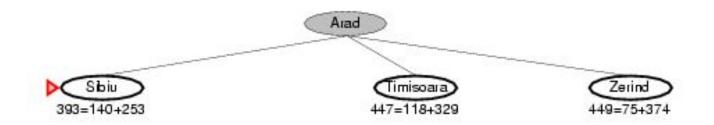

Iasi Neamt Iasi Neamt

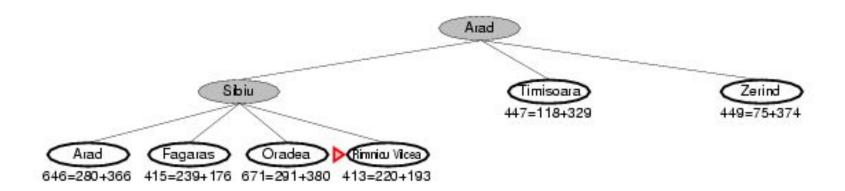

- Time? $O(b^m)$, but a good heuristic can give dramatic improvement
- Space? $O(b^m)$ -- keeps all nodes in memory
- Optimal? No

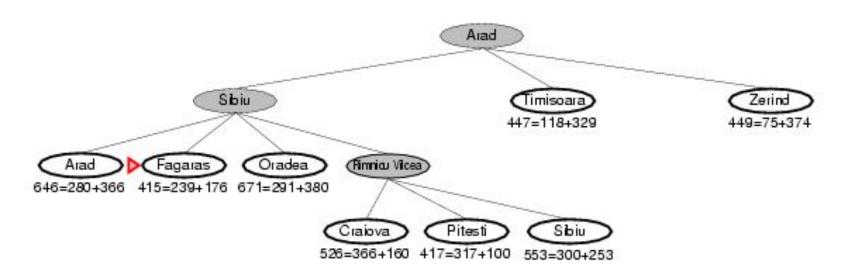

A* search

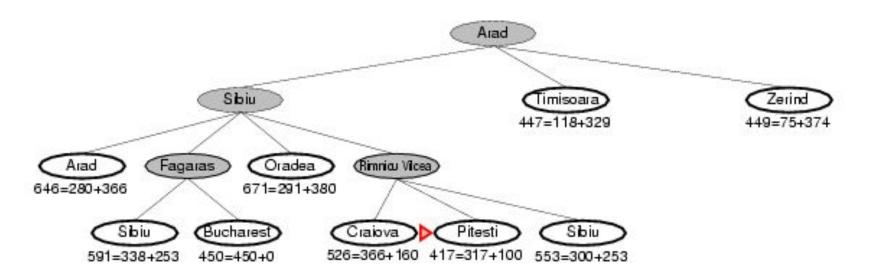

- Idea: avoid expanding paths that are already expensive
- Evaluation function f(n) = g(n) + h(n)
- $g(n) = \cos t \sin t \cos r = \cosh n$
- h(n) = estimated cost from n to goal
- f(n) = estimated total cost of path through n to goal

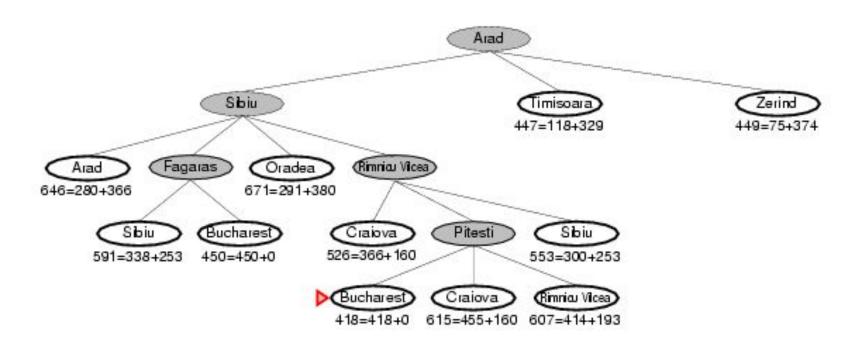

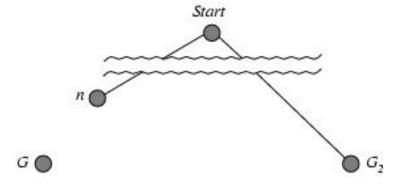

Admissible heuristics

• A heuristic h(n) is admissible if for every node n, $h(n) \le h^*(n)$, where $h^*(n)$ is the true cost to reach the goal state from n.

- An admissible heuristic never overestimates the cost to reach the goal, i.e., it is optimistic
- Example: $h_{SLD}(n)$ (never overestimates the actual road distance)
- Theorem: If h(n) is admissible, A^* using TREE-SEARCH is optimal

Optimality of A* (proof)

• Suppose some suboptimal goal G_2 has been generated and is in the fringe. Let n be an unexpanded node in the fringe such that n is on a shortest path to an optimal goal G.

- We need to show: $f(n) < f(G_2)$
- f(n) = g(n) + h(n) $\leq g(n) + c(n, G)$ since h is admissible = g(G) $< g(G_2)$ since G_2 is suboptimal $= f(G_2)$ since $h(G_2) = 0$

Properties of A*

• Complete? Yes (unless there are infinitely many nodes with $f \le f(G)$)

• <u>Time?</u> Exponential

• Space? Keeps all nodes in memory

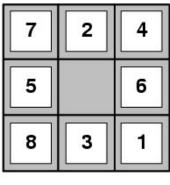

• Optimal? Yes

Admissible heuristics

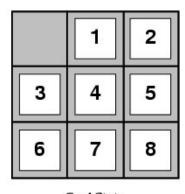

E.g., for the 8-puzzle:

- $h_1(n)$ = number of misplaced tiles
- $h_2(n)$ = total Manhattan distance

(i.e., no. of squares from desired location of each tile)

Goal State

•
$$h_1(S) = ?$$

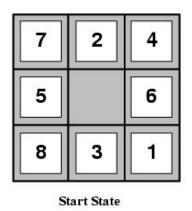

•
$$h_2(S) = ?$$

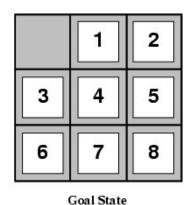

Admissible heuristics

E.g., for the 8-puzzle:

- $h_1(n)$ = number of misplaced tiles
- $h_2(n) = \text{total Manhattan distance}$

(i.e., no. of squares from desired location of each tile)

- $h_1(S) = ?8$
- $\underline{h}_2(S) = ? 3 + 1 + 2 + 2 + 2 + 3 + 3 + 2 = 18$

Dominance

- If $h_2(n) \ge h_1(n)$ for all n (both admissible)
- then h_2 dominates h_1
- b_2 is better for search
- Typical search costs (average number of nodes expanded):
- d=12 IDS = 3,644,035 nodes $A^*(h_1) = 227$ nodes $A^*(h_2) = 73$ nodes
- d=24 IDS = too many nodes $A^*(h_1) = 39,135$ nodes $A^*(h_2) = 1,641$ nodes
- Why is A* so much better?

 Because it reduces the effective branching factor

Relaxed problems

- A problem with fewer restrictions on the actions is called a relaxed problem
- The cost of an optimal solution to a relaxed problem is an admissible heuristic for the original problem
- If the rules of the 8-puzzle are relaxed so that a tile can move anywhere, then $h_1(n)$ gives the shortest solution
- If the rules are relaxed so that a tile can move to any adjacent square, then $h_2(n)$ gives the shortest solution
